Create the adjacency matrix behind the reporting network of a multi-unit organization with the following attributes

- Ten units
- One manager by unit
- Five middle managers by unit reporting to the unit manager
- Ten employees reporting to each middle manager

Then

- Visualize the adjacency matrix of the network
- Visualize the network
- Get the centralization index of the network

Some key general points emerging from the analysis of the Soundcloud example:

- The same pair of nodes can be connected because of multiple relationships (i.e., 'like,' 'repost,' 'comment')
- The nodes of a network may have the same type (e.g., 'following') or different types (e.g., 'like')
- Analytically separated networks may be correlated (e.g., one tends to like her/his followings' likes)

Key Words human ecology, voluntary associations, organizations

Abstract Similarity breeds connection. This principle—the homophily principle—structures network ties of every type, including marriage, friendship, work, advice, support, information transfer, exchange, comembership, and other types of relationship. The result is that people's personal networks are homogeneous with regard to many sociodemographic, behavioral, and intrapersonal characteristics. Homophily limits people's social worlds in way that has powerful implications for the information they receive, the attitudes they form, and the interactions they experience. Homophily in race and ethnicity creates the strongest divides in our personal environments, with age, religion, education, occupation, and gender following in roughly that order. Geographic propinquity, families, organizations, and isomorphic positions in social systems all create contexts in which homophilous relations form. Ties between nonsimilar individuals also dissolve at a higher rate, which sets the stage for the formation of niches (localized positions) within social space. We argue for more research on: (a) the basic ecological processes that link organizations, associations, cultural communities, social movements, and many other social forms; (b) the impact of multiplex ties on the patterns of homophily; and (c) the dynamics of network change over time through which networks and other social entities co-evolve.

Making the Connection: Social Bonding in Courtship Situations¹

Daniel A. McFarland and Dan Jurafsky
Stanford University

Craig Rawlings
University of California, Santa Barbara

Sociologists have long argued that the force of a social bond resides in a sense of interpersonal connection. This is especially true for initial courtship encounters when pairs report a sense of interpersonal chemistry. The authors explore the process of romantic bonding by applying interaction ritual theory, extended and integrated with methods from computational linguistics, to the study of courtship encounters and, specifically, heterosexual speed dating. The authors find that the assortment of interpersonal moves associated with a sense of connection characterizes a conventionalized form of initial courtship activity. The game is successfully played when females are the point of focus and engaged in the conversation and males demonstrate alignment with and understanding of the female. In short, initial heterosexual courtship encounters are associated with a sense of bonding when they reflect a reciprocal asymmetrical performance in which differentiated roles are mutually coordinated.

INTRODUCTION

Social bonds are a central topic of sociology because they are the social glue of society. What renders social bonds distinct from other forms of inter-

Getting by with the Advice of Their Friends: CEOs' Advice Networks and Firms' Strategic Responses to Poor Performance

Michael L. McDonald
James D. Westphal
University of Texas at Austin

This paper theorizes that relatively poor firm performance can prompt chief executive officers (CEOs) to seek more advice from executives of other firms who are their friends or similar to them and less advice from acquaintances or dissimilar others and suggests how and why this pattern of advice seeking could reduce firms' propensity to change corporate strategy in response to poor performance. We test our hypotheses with large-sample survey data on the identities of CEOs' advice contacts and archival data on firm performance and corporate strategy. The results confirm our hypotheses and show that executives' social network ties can influence firms' responses to economic adversity, in particular by inhibiting strategic change in response to relatively poor firm performance. Additional findings indicate that CEOs' advice seeking in response to low performance may ultimately have negative consequences for subsequent performance, suggesting how CEOs' social network ties could play an indirect role in organizational decline and downward spirals in firm performance.●

References

Let's consider a network containing a fraction p of male nodes (m) and a fraction q of female nodes (f), and denote the link between nodes i and j as $e_{i,j}$.

The no-homophily hypothesis implies what follows:

- 1 $pr(e_{ij} \mid i = m, j = m) = p * p$
- 2 $pr(e_{ij} \mid i = f, j = f) = q * q$
- 3 $pr(e_{ij} \mid i = m, j = f) = p * q$
- 4 $pr(e_{ij} \mid i = f, j = m) = q * p$

If the proportion of male-female ties deviates from $2 * (p * q)$, then there is evidence of homophily in the network.

References

There are two mechanisms through which homophily affects tie formation:

- **Selection:** individual bond with others they perceive 'similar' on salient dimensions
- **Socialization:** individuals that directly, closely, frequently interact with each other become more and more 'similar'

Note: The relative strength of 'selection' and 'socialization' largely depends on the attributes individuals use to assess interpersonal similarity. Socialization does not operate for fixed demographic factors, whereas it plays a central role when attitudes or behavior are used as a basis for similarity

The adoption of new ideas, styles, technologies, products, or, in general behaviors, is subject to direct-benefit effects

- The benefits to 'ego' of adopting a new behavior increase as more and more 'neighbors' adopt it
- The implication is that an individual adopts a certain behavior once a sufficient proportion of her/his neighbors have done so
 - For example, you may find it easier to collaborate with co-workers, if you are using compatible technologies

- We will study a situation in which each node has a choice between two possible behaviors, labeled A and B
- If nodes v and w are linked by an edge, then there is an incentive for them to have their behaviors match
- If v and w both adopt behavior A , they each get a payoff of $a > 0$
- If they both adopt B , they each get a payoff of $b > 0$
- If they adopt opposite behaviors, they each get a payoff of 0
- Each node v is playing a copy of this game with each of its neighbors, and its payoff is the sum of its payoffs in the games played on each edge

- The basic question faced by v will be the following: suppose that some of its neighbors adopt A , and some adopt B ; what should v do in order to maximize its payoff?
- Suppose that a p fraction of v 's neighbors have behavior A , and a $(1 - p)$ fraction have behavior B
 - If v has d neighbors, then pd adopt A and $(1p)d$ adopt B
 - If v chooses A , it gets a payoff of pda , and if it chooses B , it gets a payoff of $(1p)db$
- A is the better choice if:

$$pda \geq (1 - p)db \quad (1)$$

that is,

$$p \geq \frac{b}{a + b} \quad (2)$$
